 Introduction Introduction Operational experience [Kent] [Huston] [RFC7872] reveals that IP Operational experience [Kent] [Huston] [RFC7872] reveals that IP fragmentation introduces fragility to Internet communication. This fragmentation introduces fragility to Internet communication. This document describes IP fragmentation and explains the fragility it document describes IP fragmentation and explains the fragility it introduces. It also proposes alternatives to IP fragmentation and provides recommendations for developers and network operators. introduces. It also proposes alternatives to IP fragmentation and provides recommendations for developers and network operators. While this document identifies issues associated with IP While this document identifies issues associated with IP fragmentation, it does not recommend deprecation. Legacy protocols that depend upon IP fragmentation SHOULD be updated to remove that fragmentation, it does not recommend deprecation. Legacy protocols that depend upon IP fragmentation SHOULD be updated to remove that dependency. However, some application should be updated to remove that dependency. However, some applications and environments (see Section 5) require IP fragmentation. In these cases, the protocol will continue to rely on IP fragmentation, but the designer should to be aware that fragmented packets may result in blackholes; a design dependency. However, some applications and environments (see Section 6) require IP fragmentation. In these cases, the protocol will continue to rely on IP fragmentation, but the designer should to be aware that fragmented packets may result in blackholes; a design should include appropriate safeguards. should include appropriate safeguards. Rather than deprecating IP Fragmentation, this document recommends Rather than deprecating IP Fragmentation, this document recommends that upper-layer protocols address the problem of fragmentation at their layer, reducing their reliance on IP fragmentation to the that upper-layer protocols address the problem of fragmentation at their layer, reducing their reliance on IP fragmentation to the greatest degree possible. greatest degree possible. 1.1. IP-in-IP Tunnels 1.1. IP-in-IP Tunnels This document acknowledges that in some cases, packets must be This document acknowledges that in some cases, packets must be fragmented within IP-in-IP tunnels [I-D.ietf-intarea-tunnels]. fragmented within IP-in-IP tunnels [I-D.ietf-intarea-tunnels]. Therefore, this document makes no additional recommendations Therefore, this document makes no additional recommendations regarding IP-in-IP tunnels. regarding IP-in-IP tunnels. 1.2. Requirements Language The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here. IP Fragmentation IP Fragmentation 2.1. Links, Paths, MTU and PMTU 2.1. Links, Paths, MTU and PMTU An Internet path connects a source node to a destination node. Α An Internet path connects a source node to a destination node. A path can contain links and routers. If a path contains more than one path can contain links and routers. If a path contains more than one link, the links are connected in series and a router connects each link, the links are connected in series and a router connects each link to the next. link to the next. Internet paths are dynamic. Assume that the path from one node to Internet paths are dynamic. Assume that the path from one node to skipping to change at *page 5, line 34* skipping to change at *page 5, line 45* whose length is equal to 576 bytes. However, the IPv4 minimum link MTU is not 576. Section 3.2 of RFC 791 explicitly states that the IPv4 minimum link MTU is 68 bytes. But for practical purposes, many network operators consider the IPv4 minimum link MTU to be 576 bytes, to minimize the requirement for fragmentation en route. So, for the whose length is equal to 576 bytes. However, the IPv4 minimum link MTU is not 576. Section 3.2 of RFC 791 explicitly states that the IPv4 minimum link MTU is 68 bytes. But for practical purposes, many network operators consider the IPv4 minimum link MTU to be 576 bytes, to minimize the requirement for fragmentation en route. So, for the purposes of this document, we assume that the IPv4 minimum path MTU is 576 bytes. purposes of this document, we assume that the IPv4 minimum path MTU is 576 bytes. NOTE 2: A non-fragmentable packet can be fragmented at its source. However, it cannot be fragmented by a downstream node. An IPv4 packet whose DF-bit is set to (0) is fragmentable. An IPv4 packet whose DF-bit is set to (1) is non-fragmentable. All IPv6 packets are NOTE 2: A non-fragmentable packet can be fragmented at its source. However, it cannot be fragmented by a downstream node. An IPv4 packet whose DF-bit is set to zero is fragmentable. An IPv4 packet whose DF-bit is set to one is non-fragmentable. All IPv6 packets are also non-fragmentable. also non-fragmentable. NOTE 3:: The ICMP PTB message has two instantiations. In ICMPv4 NOTE 3:: The ICMP PTB message has two instantiations. In ICMPv4 [RFC0792], the ICMP PTB message is a Destination Unreachable message [RFC0792], the ICMP PTB message is a Destination Unreachable message [RFC0792], the ICMP PIB message is a Destination Unreachable message with Code equal to (4) fragmentation needed and DF set. This message was augmented by [RFC1191] to indicate the MTU of the link through which the packet could not be forwarded. In ICMPv6 [RFC4443], the ICMP PIB message is a Packet Too Big Message with Code equal to (0). This message also indicates the MTU of the link through which the packet equal on the forwarded. with Code equal to (4) fragmentation needed and DF set. This message was augmented by [RFC1191] to indicate the MTU of the link through which the packet could not be forwarded. In ICMPv6 [RFC1443], the ICMP TB message is a Packet Too Big Message with Code equal to (0). This message also indicates the MTU of the link through which the packet could not be forwarded. packet could not be forwarded. 2.2. Fragmentation Procedures 2.2. Fragmentation Procedures When an upper-layer protocol submits data to the underlying IP module, and the resulting IP packet's length is greater than the PMTU, the packet is divided into fragments. Each fragment includes an IP header and a portion of the original packet. When an upper-layer protocol submits data to the underlying IP module, and the resulting IP packet's length is greater than the PMTU, the packet is divided into fragments. Each fragment includes an IP header and a portion of the original packet. [RFC0791] describes IPv4 fragmentation procedures. An IPv4 packet [RFC0791] describes IPv4 fragmentation procedures. An IPv4 packet [RFC0/91] describes IPV4 fragmentation procedures. An IPV4 packet whose DF-bit is set to (1) can be fragmented by the source node, but cannot be fragmented by a downstream router. An IPv4 packet whose DF-bit is set to (0) can be fragmented by the source node or by a downstream router. When an IPv4 packet is fragmented, all IP options appear in the first fragment, but only options whose "copy" bit is whose DF-bit is set to one can be fragmented by the source node, but cannot be fragmented by a downstream router. An IPv4 packet whose DF-bit is set to zero can be fragmented by the source node or by a downstream router. When an IPv4 packet is fragmented, all IP options appear in the first fragment, but only options whose "copy" bit is set to one appear in subsequent fragments. set to (1) appear in subsequent fragments. [RFC8200] describes IPv6 fragmentation procedures. An IPv6 packet [RFC8200] describes IPv6 fragmentation procedures. An IPv6 packet can be fragmented at the source node only. When an IPv6 packet is fragmented, all extension headers appear in the first fragment, but only per-fragment headers appear in subsequent fragments. Per-fragment headers include the following: can be fragmented at the source node only. When an IPv6 packet is fragmented, all extension headers appear in the first fragment, but only per-fragment headers appear in subsequent fragments. Per-fragment headers include the following: o The IPv6 header. o The IPv6 header. o The Hop-by-hop Options header (if present) o The Hop-by-hop Options header (if present)

skipping to change at page 7, line 20 [I-D.ietf-tsvwg-datagram-plpmtud] procedures. skipping to change at page 7, line 33 [I-D.ietf-tsvwg-datagram-plpmtud] procedures.

According to PLPMTUD procedures, the upper-layer protocol maintains a		
running PMTU estimate. It does so by sending probe packets of various sizes to its upper-layer peer and receiving acknowledgements. This strategy differs from PMTUD in that it relies on acknowledgement of received messages, as opposed to ICMP PTB messages concerning dropped messages. Therefore, FLPMTUD does not rely on the network's ability to deliver ICMP PTB messages to the source.	According to PLPMTUD procedures, the upper-layer protocol maintains a running PMTU estimate. It does so by sending probe packets of various sizes to its upper-layer peer and receiving acknowledgements. This strategy differs from PMTUD in that it relies on acknowledgement of received messages, as opposed to ICMP PTB messages concerning dropped messages. Therefore, PLPMTUD does not rely on the network's ability to deliver ICMP PTB messages to the source.	
3. Requirements Language	3. Increased Fragility	
The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.		
4. Increased Fragility		
This section explains how IP fragmentation introduces fragility to Internet communication.	This section explains how IP fragmentation introduces fragility to Internet communication.	
4.1. Policy-Based Routing	3.1. Virtual Reassembly	
	Virtual reassembly is a procedure in which a device reassembles a packet, forwards its fragments, and discards the reassembled copy. In A+P and CGN, virtual reassembly is required in order to correctly translate fragment addresses. It can be useful in Section 3.2, Section 3.3, Section 3.4, and Section 3.5.	
	Virtual reassembly in the network is problematic, however, because it is computationally expensive and because it holds state for indeterminate periods of time, is prone to errors and, is prone to attacks (Section 3.7).	
	3.2. Policy-Based Routing	
IP Fragmentation causes problems for routers that implement policy- based routing.	IP Fragmentation causes problems for routers that implement policy- based routing.	
When a router receives a packet, it identifies the next-hop on route to the packet's destination and forwards the packet to that next-hop. In order to identify the next-hop, the router interrogates a local data structure called the Forwarding Information Base (FIB).	When a router receives a packet, it identifies the next-hop on route to the packet's destination and forwards the packet to that next-hop. In order to identify the next-hop, the router interrogates a local data structure called the Forwarding Information Base (FIB).	
Normally, the FIB contains destination-based entries that map a	Normally, the FIB contains destination-based entries that map a	
skipping to change at <i>page 8, line 42</i>	skipping to change at <i>page 9, line 9</i>	
When the router receives the second fragment of the packet, it interrogates the FIB again. This time, only the first FIB entry satisfies the query, because the second fragment contains no indication that the packet is destined for TCP port 80. Therefore, the router selects the first FIB entry and forwards the packet to 2001:db8::2.	When the router receives the second fragment of the packet, it interrogates the FIB again. This time, only the first FIB entry satisfies the query, because the second fragment contains no indication that the packet is destined for TCP port 80. Therefore, the router selects the first FIB entry and forwards the packet to 2001:db8::2.	
Policy-based routing is also known as filter-based-forwarding.	Policy-based routing is also known as filter-based-forwarding.	
1.2. Network Address Translation (NAT)		
	3.3. Network Address Translation (NAT)	
IP fragmentation causes problems for Network Address Translation (NAT) devices. When a NAT device detects a new, outbound flow, it maps that flow's source port and IP address to another source port and IP address. Having created that mapping, the NAT device translates:	3.3. IP fragmentation causes problems for Equal Cost Multipath (ECMP), Link Aggregate Groups (LAG) and other stateless load-balancing technologies. In order to assign a packet or packet fragment to a link, an intermediate node executes a hash (i.e., load-balancing) algorithm. The following paragraphs describe a commonly deployed hash algorithm.

If the packet or packet fragment contains a transport-layer header,

skipping to change at page 10, line 39 algorithm used to determine the outgoing component-link in an ECMP and/or LAG toward the next hop MUST minimally include the 3-tuple {dest addr, source addr, flow label} and MAY also include the remaining components of the 5-tuple."

If the algorithm includes only the 3-tuple {dest addr, source addr, flow label}, it will assign all fragments belonging to a packet to the same link. (See [RFC6437] and [RFC7098]).

In order to avoid the problem described above, implementations SHOULD implement the recommendations provided in Section 7.4 of this document.

4.5. IPv4 Reassembly Errors at High Data Rates

IPv4 fragmentation is not sufficiently robust for use under some conditions in today's Internet. At high data rates, the 16-bit IP identification field is not large enough to prevent frequent incorrectly assembled IP fragments, and the TCP and UDP checksums are insufficient to prevent the resulting corrupted datagrams from being delivered to higher protocol layers. [RFC4963] describes some easily reproduced experiments demonstrating the problem, and discusses some of the operational implications of these observations.

These reassembly issues are not easily reproducible in IPv6 because the IPv6 identification field is 32 bits long.

4.6. Security Vulnerabilities

Security researchers have documented several attacks that exploit IP fragmentation. The following are examples:

- o Overlapping fragment attacks [RFC1858][RFC3128][RFC5722]
- o Resource exhaustion attacks
- Attacks based on predictable fragment identification values [RFC7739]

skipping to change at page 12, line 14 for an attacker to forge malicious IP fragments that would cause the reassembly procedure for legitimate packets to fail.

NIDS aims at identifying malicious activity by analyzing network traffic. Ambiguity in the possible result of the fragment reassembly process may allow an attacker to evade these systems. Many of these systems try to mitigate some of these evasion techniques (e.g. By computing all possible outcomes of the fragment reassembly process, at the expense of increased processing requirements).

4.7. PMTU Blackholing Due to ICMP Loss

As mentioned in Section 2.3, upper-layer protocols can be configured to rely on PMTUD. Because PMTUD relies upon the network to deliver ICMP PTB messages, those protocols also rely on the networks to deliver ICMP PTB messages.

According to [RFC4890], ICMP PTB messages must not be filtered. However, ICMP PTB delivery is not reliable. It is subject to both transient and persistent loss.

Transient loss of ICMP PTB messages can cause transient PMTU black holes. When the conditions contributing to transient loss abate, the network regains its ability to deliver ICMP PTB messages and connectivity between the source and destination nodes is restored. Section 4.7.1 of this document describes conditions that lead to transient loss of ICMP PTB messages.

Persistent loss of ICMP PTB messages can cause persistent black holes. Section 4.7.2, Section 4.7.3, and Section 4.7.4 of this document describe conditions that lead to persistent loss of ICMP PTB messages.

The problem described in this section is specific to PMTUD. It does not occur when the upper-layer protocol obtains its PMTU estimate from PLPMTUD or from any other source.

4.7.1. Transient Loss

The following factors can contribute to transient loss of ICMP PTB messages:

- o Network congestion.
- o Packet corruption.
- o Transient routing loops.
- o ICMP rate limiting.

IP fragmentation causes problems for Equal Cost Multipath (ECMP), Link Aggregate Groups (LAC) and other stateless load-balancing technologies. In order to assign a packet or packet fragment to a link, an intermediate node executes a hash (i.e., load-balancing) algorithm. The following paragraphs describe a commonly deployed hash algorithm.

If the packet or packet fragment contains a transport-layer header,

skipping to change at page 10, line 46 algorithm used to determine the outgoing component-link in an ECMP and/or LAG toward the next hop MUST minimally include the 3-tuple {dest addr, source addr, flow label} and MAY also include the remaining components of the 5-tuple."

If the algorithm includes only the 3-tuple {dest addr, source addr, flow label}, it will assign all fragments belonging to a packet to the same link. (See [RFC6437] and [RFC7098]).

In order to avoid the problem described above, implementations SHOULD implement the recommendations provided in Section 6.4 of this document.

3.6. IPv4 Reassembly Errors at High Data Rates

IPv4 fragmentation is not sufficiently robust for use under some conditions in today's Internet. At high data rates, the 16-bit IP identification field is not large enough to prevent **duplicate IDs resulting in** frequent incorrectly assembled IP fragments, and the TCP and UDP checksums are insufficient to prevent the resulting corrupted datagrams from being delivered to higher protocol layers. [RFC4963] describes some easily reproduced experiments demonstrating the problem, and discusses some of the operational implications of these observations.

These reassembly issues do not occur as frequently in IPv6 because the IPv6 identification field is 32 bits long.

3.7. Security Vulnerabilities

Security researchers have documented several attacks that exploit IP fragmentation. The following are examples:

- o Overlapping fragment attacks [RFC1858][RFC3128][RFC5722]
- o Resource exhaustion attacks
- o Attacks based on predictable fragment identification values $\ensuremath{\left[\text{RFC7739}\right]}$

skipping to change at page 12, line 28 for an attacker to forge malicious IP fragments that would cause the reassembly procedure for legitimate packets to fail.

NIDS aims at identifying malicious activity by analyzing network traffic. Ambiguity in the possible result of the fragment reassembly process may allow an attacker to evade these systems. Many of these systems try to mitigate some of these evasion techniques (e.g. By computing all possible outcomes of the fragment reassembly process, at the expense of increased processing requirements).

3.8. PMTU Blackholing Due to ICMP Loss

As mentioned in Section 2.3, upper-layer protocols can be configured to rely on PMTUD. Because PMTUD relies upon the network to deliver ICMP PTB messages, those protocols also rely on the networks to deliver ICMP PTB messages.

According to [RFC4890], ICMP PTB messages must not be filtered. However, ICMP PTB delivery is not reliable. It is subject to both transient and persistent loss.

Transient loss of ICMP PTB messages can cause transient PMTU black holes. When the conditions contributing to transient loss abate, the network regains its ability to deliver ICMP PTB messages and connectivity between the source and destination nodes is restored. Section 3.8.1 of this document describes conditions that lead to transient loss of ICMP PTB messages.

Persistent loss of ICMP PTB messages can cause persistent black holes. Section 3.8.2, Section 3.8.3, and Section 3.8.4 of this document describe conditions that lead to persistent loss of ICMP PTB messages.

The problem described in this section is specific to PMTUD. It does not occur when the upper-layer protocol obtains its PMTU estimate from PLPMTUD or from any other source.

3.8.1. Transient Loss

The following factors can contribute to transient loss of ICMP $\ensuremath{\texttt{PTB}}$ messages:

- o Network congestion.
- o Packet corruption.
- o Transient routing loops.
- o ICMP rate limiting.

The effect of rate limiting may be severe, as RFC 4443 recommends strict rate limiting of IPv6 traffic.	The effect of rate limiting may be severe, as RFC 4443 recommends strict rate limiting of IPv6 traffic.		
.7.2. Incorrect Implementation of Security Policy	3.8.2. Incorrect Implementation of Security Policy		
Incorrect implementation of security policy can cause persistent loss of ICMP PTB messages.	Incorrect implementation of security policy can cause persistent los of ICMP PTB messages.		
Assume that a Customer Premise Equipment (CPE) router implements the following zone-based security policy:	Assume that a Customer Premise Equipment (CPE) router implements the following zone-based security policy:		
o Allow any traffic to flow from the inside zone to the outside zone.	o Allow any traffic to flow from the inside zone to the outside zone.		
skipping to change at page 13, line 40	skipping to change at page 14, line 8		
allows the ICMP PTB to flow from the outside zone to the inside zone. If not, the implementation discards the ICMP PTB message.	allows the ICMP PTB to flow from the outside zone to the inside zone If not, the implementation discards the ICMP PTB message.		
When a incorrect implementation of the above-mentioned security policy receives an ICMP PTB message, it discards the packet because its source address is not associated with an existing flow.	When a incorrect implementation of the above-mentioned security policy receives an ICMP PTB message, it discards the packet because its source address is not associated with an existing flow.		
The security policy described above is implemented incorrectly on many consumer CPE routers.	The security policy described above is implemented incorrectly on many consumer CPE routers.		
.7.3. Persistent Loss Caused By Anycast	3.8.3. Persistent Loss Caused By Anycast		
Anycast can cause persistent loss of ICMP PTB messages. Consider the example below:	Anycast can cause persistent loss of ICMP PTB messages. Consider th example below:		
A DNS client sends a request to an anycast address. The network routes that DNS request to the nearest instance of that anycast address (i.e., a DNS Server). The DNS server generates a response and sends it back to the DNS client. While the response does not exceed the DNS server's PMTU estimate, it does exceed the actual PMTU.	A DNS client sends a request to an anycast address. The network routes that DNS request to the nearest instance of that anycast address (i.e., a DNS Server). The DNS server generates a response and sends it back to the DNS client. While the response does not exceed the DNS server's PMTU estimate, it does exceed the actual PMTU.		
A downstream router drops the packet and sends an ICMP PTB message the packet's source (i.e., the anycast address). The network routes the ICMP PTB message to the anycast instance closest to the downstream router. That anycast instance may not be the DNS server that originated the DNS response. It may be another DNS server with the same anycast address. The DNS server that originated the response may never receive the ICMP PTB message and may never update its PMTU estimate.	A downstream router drops the packet and sends an ICMP PTB message the packet's source (i.e., the anycast address). The network routes the ICMP PTB message to the anycast instance closest to the downstream router. That anycast instance may not be the DNS server that originated the DNS response. It may be another DNS server with the same anycast address. The DNS server that originated the response may never receive the ICMP PTB message and may never update its PMTU estimate.		
.7.4. Persistent Loss Caused By Unidirectional Routing	3.8.4. Persistent Loss Caused By Unidirectional Routing		
Unidirectional routing can cause persistent loss of ICMP PTB messages. Consider the example below:	Unidirectional routing can cause persistent loss of ICMP PTB messages. Consider the example below:		
A source node sends a packet to a destination node. All intermediate nodes maintain a route to the destination node, but do not maintain a route to the source node. In this case, when an intermediate node encounters an MTU issue, it cannot send an ICMP PTB message to the source node.	A source node sends a packet to a destination node. All intermediat nodes maintain a route to the destination node, but do not maintain route to the source node. In this case, when an intermediate node encounters an MTU issue, it cannot send an ICMP PTB message to the source node.		
.8. Blackholing Due To Filtering or Loss	3.9. Blackholing Due To Filtering or Loss		
In RFC 7872, researchers sampled Internet paths to determine whether they would convey packets that contain IPv6 extension headers. Sampled paths terminated at popular Internet sites (e.g., popular web, mail and DNS servers). 7.2. For System Developers

Some UDP applications rely on IP fragmentation to achieve acceptable levels of performance. These applications use UDP datagram sizes that are larger than the path MTU so that more data can be conveyed between the application and the kernel in a single system call.

To pick one example, the Licklider Transmission Protocol (LTP), [RFC5326] which is in current use on the International Space Station (ISS), uses UDP datagram sizes larger than the path MTU to achieve acceptable levels of performance even though this invokes IP fragmentation. More generally, SNMP and video applications may transmit an application-layer guantum of data, depending on the network layer to fragment and reassemble as needed.

More generally, SNMP and video applications may transmit an application-layer quantum of data, depending on the network layer to fragment and reassemble as needed.

Recommendations

6.1. For Application and Protocol Developers

Developers SHOULD NOT develop new protocols or applications that rely on IP fragmentation. When a new protocol or application is deployed in an environment that does not fully support IP fragmentation, it SHOULD operate correctly, either in its default configuration or in a specified alternative configuration.

Developers MAY develop new protocols or applications that rely on IP fragmentation if the protocol or application is to be run only in environments where IP fragmentation is known to be supported.

skipping to change at *page 20, line 5*

Protocols may be able to avoid IP fragmentation by using a sufficiently small MTU (e.g. The protocol minimum link MTU), disabling IP fragmentation, and ensuring that the transport protocol in use adapts its segment size to the MTU. Other protocols may deploy a sufficiently reliable PMTU discovery mechanism (e.g.,PLMPTUD).

UDP applications SHOULD abide by the recommendations stated in Section 3.2 of [RFC8085].

6.2. For System Developers

Software libraries SHOULD include provision for PLPMTUD for each supported transport protocol

For Middle Box Developers

Middle boxes should process IP fragments in a manner that is consistent with [RFC0791] and [RFC0200]. In many cases, middle boxes must maintain state in order to achieve this goal.

Price and performance considerations frequently motivate network Price and performance considerations frequently motivate network operators to deploy stateless middle boxes. These stateless middle boxes may perform sub-optimally, process IP fragments in a manner that is not compliant with RFC 791 or RFC 8200, or even discard IP fragments completely. Such behaviors are NOT RECOMMENDED. If a middleboxes implements non-standard behavior with respect to IP fragmentation, then that behavior MUST be clearly documented.

6.4. For ECMP, LAG and Load-Balancer Developers And Operato

In their default configuration, when the IPv6 Flow Label is not equal to zero, IPv6 devices that implement Equal-Cost Multipath (ECMP) Routing as described in OSPF [RFC2328] and other routing protocols, Link Aggregation Grouping (LAG) [RFC7242], or other load-balancing technologies SHOULD accept only the following fields as input to their hash algorithm:

- o IP Source Address.
- o TP Destination Address.
- o Flow Label.

Operators SHOULD deploy these devices in their default configuration.

These recommendations are similar to those presented in [RFC6438] and [RFC7098]. They differ in that they specify a default configuration.

6.5. For Network Operators

Operators MUST ensure proper PMTUD operation in their network, including making sure the network generates PTB packets when dropping packets too large compared to outgoing interface MTU. However, implementations MAY rate limit ICMP messages as per [RFC1812] and [RFC4443].

As per RFC 4890, network operators MUST NOT filter ICMPv6 PTB messages unless they are known to be forged or otherwise illegitimate. As stated in Section 3.8, filtering ICMPv6 PTB packets causes PMTUD to fail. Many upper-layer protocols rely on PMTUD.

As per RFC 8200, network operators MUST NOT deploy IPv6 links whose MTU is less than 1280 bytes.

Network operators SHOULD NOT filter IP fragments if they are known to have originated at a domain name server or be destined for a domain This is because domain name services are critical to name server. operation of the Internet.

IANA Considerations 7.

This document makes no request of IANA.

9. Security Considerations		8. Security Considerations		
This document mitigates some of the security considerations associated with IP fragmentation by discouraging its use. It does not introduce any new security vulnerabilities, because it does not introduce any new alternatives to IP fragmentation. Instead, it recommends well-understood alternatives.
